Calculate your stocking rate.

Once you know your animals’ requirements, and your land’s production, it is easy to estimate how much forage you have available for your livestock. You will need the following numbers:

- Pasture Size ________ acres
- Pasture Production _______ lbs/acre
- Animal Requirements ________ lbs/day

**Example**

Assumptions:
- 30 acres Foothills & Basins West native range
- 10-14 inch precip zone
- Loamy range site
- Big Sagebrush-Rhizomatous Wheatgrass Plant Community

Predicted plant production:
- Favorable precip year = 800 lbs/acre
- Average precip year = 500 lbs/acre
- Poor precip year = 100 lbs/acre

1,200 lb horse will eat 36 lbs of dry matter/day

In an average year this pasture will produce 15,000 lbs of forage. (500 lbs/acre x 30 acres)

*Half of this must be left in place to keep the plants healthy, and 15% will be lost to other grazers (deer, antelope, rabbits, mice, etc.). So only 35% of this is available to domestic animals.*

This pasture has 5,250 lbs of available forage (15,000 lbs x .35) and can support one 1,200 lb horse for 145 days (5,250 lbs / 36 lbs/day) or three 1,200 lb horses for 48 days (5,250 lbs / 108 lbs/day).

This brochure was made possible through a grant from the Wyoming Private Grazing Lands Team.

This brochure is at www.barnyardsandbackyards.com.

The University of Wyoming and the United States Department of Agriculture cooperate. The University is an equal opportunity/affirmative action institution.
Small Acreage Grazing

As Wyoming county populations grow, more and more people are purchasing and building homes on land parcels ranging in size from one to 40 acres. Many of these buyers desire to own livestock for hobby, pleasure, or 4-H agricultural projects. Animals grazing on small acres can create a large number of resource problems that people may not be aware of. These problems include a shortage of grass cover resulting in soil erosion, reduced soil quality, reduced livestock health, and increased weed species. This brochure is designed to help landowners properly care for livestock on small acres and still conserve soil, protect palatable forages, and preserve water quality.

What is Overgrazed?

Overgrazed is the term used to indicate a degraded condition and composition of the plant community as a result of grazing impact. Specific indicators of an overgrazed pasture include lack of vegetation, or a shift in types of plants away from those desirable to livestock, weed infestations, compacted soil, stunted plants, reduced plant health, excess runoff and erosion, bare soil, and lack of organic matter.

Natural Resource Problems with Overgrazing

**Soil:** Overgrazing causes reduced soil fertility rates and low soil infiltration rates. These problems are indicated by excess runoff, erosion, hard and dry soil.

**Water:** Overgrazing can contribute to water pollution because of increased runoff carrying manure and sediment, and hungry animals spending more time in higher forage producing areas near streams and reservoirs (increasing the likelihood of fecal contamination).

**Air:** Overgrazing reduces plant cover which can cause air pollution in the form of dust storms.

**Plants:** Desirable plants in an overgrazed pasture will be negatively impacted. Plants with a higher relative forage value, or those that are palatable to livestock will be grazed more intensely. This will make them less competitive against low quality forage plants and noxious weeds.

How much does your livestock eat every day?

- Forage required by an animal is commonly measured in Animal Units or an AU. It is a way to compare different animals and their feed requirements.
- One mature pleasure horse will eat approximately 35 lbs of grass or hay per day (1.25 AU).
- A 1,000 lb cow not lactating will require approximately 25 pounds of grass or hay per day (1.00 AU).
- A mature ewe or doe goat will eat 4-5 pounds of grass or hay per day (0.2 AU).
- Alpaca requirements are similar to those of sheep.

During winter months, or whenever forage quality is decreased, supplemental feed is required. This may be in the form of a complete feed, a grain, or a protein supplement. Replacement feed in the form of hay, may also be required if there is insufficient forage available.

How much does your land produce every year?

In order to estimate the amount of forage your land will produce in a year there are 3 things you need to know: ecological site precipitation zone, soil type, and present plant community. With these 3 things you can look at references from the Natural Resources Conservation Service (NRCS) and find an estimate of the forage production capacity of your land. The Lincoln Conservation District or the UW Cooperative Extension Service Office can help you determine your ecological site precipitation zone and provide the NRCS references to you!

Lincoln County has several ecological site precipitation zones. They are Green River & Great Divide Basin with 7-9” of annual precip, Foothills & Basins West with 10-14” annual precip, Foothills and Mtns. West with 15-19” annual precip and High Mountains with 20+” annual precip.

The next page has an example of what a production table looks like for the Foothills & Basins West 10-14” precipitation zone, on loamy soil.
