

### III. Transcription

- an **operon** at which the transcription complex assembles
- In bacteria, **operons** may be under control of the same promoter. This is called an **operon**. mRNAs formed will carry the information for more than one gene and are thus called **polycistronic mRNAs**.
- In eukaryotes, generally **each gene** has its own promoter. mRNAs carry the information for only one gene and are termed **monocistronic mRNAs**.

Promoters have **consensus sequences** (hypothetical sequences made up of nucleotides found most often in each position). For prokaryotic promoters:

5' ... TTGACA ..... TATAAT ..... **Start site**

If a promoter very **resembles** the consensus sequence (a **strong promoter**), then the gene/genes downstream are very **efficiently** transcribed. If the match is quite poor then the promoter is **weak** and the gene/genes are transcribed quite **poorly**.

**Genes downstream of which promoter would be transcribed the most frequently?**

**5' TTCACA.....TATTTT.....start site**

**5' TACACA.....TAATTT.....start site**

**5' TTGAGA.....TATATT.....start site**

## All of the following accurately describe either prokaryotic replication or transcription EXCEPT?

- a.** During replication, Okazaki fragments are formed during the synthesis of the lagging strand of DNA but not during the synthesis of the leading strand.
- b.** The next deoxynucleoside triphosphate that DNA polymerase would add to the currently synthesizing strand would be dCTP.

- c.** A promoter with the -35 sequence of TGCAGA and a -10 sequence of TATTGT is stronger than a promoter with a -35 sequence of TTGAGA and a -10 sequence of TATATT.
- d.** The coding strand of DNA has the same sequence as the RNA transcript only Us replace Ts in the RNA.

A promoter is \_\_\_\_\_ of a gene

### A. Initiation

The diagram shows the DNA double helix from the previous slide. An orange circular complex representing RNA polymerase is bound to the promoter region (yellow segment). A green dot is visible within the complex, representing the sigma factor. The DNA strands are labeled 5' and 3' at their respective ends.

- The \_\_\_\_\_ of RNA polymerase allows the holoenzyme to bind tightly to the promoter.
- Binding of RNA polymerase \_\_\_\_\_ and \_\_\_\_\_ a short stretch (16-20 bp) of DNA called the \_\_\_\_\_.
- A short stretch of complementary RNA (~ 9 nucleotides) is \_\_\_\_\_.

B.

1. RNA polymerase moves along the template strand at a time.

b. As RNA polymerase moves, the previous stretch of DNA and the current stretch is

2. As soon as RNA polymerase has left the promoter region, a new RNA polymerase enzyme can bind and start a

C.

## Transcription termination

### Termination due to formation

A DNA sequence encodes for two complementary regions of RNA. These regions hydrogen-bond and form a loop that causes RNA polymerase to leave the template.

### termination

The rho enzyme

destabilizing the RNA-DNA hybrid and causing termination.

## IV. Translation

Recall the structure of an amino acid:

- During translation, amino acids are added to the
- Each amino acid is specified by a 3-nucleotide sequence (called a ) on the mRNA.

The Players:

1. mRNA

The codons:

- a. Three of the codons are  
 b. The other 61 codons each specify a particular amino acid. Since there are only 20 amino acids, this means that

Second position						
	U	C	A	G		
First position	U	UUU <b>Phe</b> UUC UUA <b>Leu</b> UUG	UCU UCC UCA UCG	UAU <b>Tyr</b> UAC	UGU <b>Cys</b> UGC  UGG <b>Trp</b>	U C A G
	C	CUU CUC <b>Leu</b> CUA CUG	CCU CCC CCA CCG	CAU <b>His</b> CAC CAA <b>Gln</b> CAG	CGU CGC <b>Arg</b> CGA CGG	U C A G
	A	AUU AUC <b>Ile</b> AUA	ACU ACC ACA ACG	AAU <b>Asn</b> AAC AAA <b>Lys</b> AAG	AGU <b>Ser</b> AGC AGA <b>Arg</b> AGG	U C A G
	G	GUU GUC GUA GUG	GCU GCC <b>Ala</b> GCA GCG	GAU GAC GAA GAG	GGU GGC <b>Gly</b> GGA GGG	U C A G

c. The mRNA also carries the information that indicates  
That is, it specifies

**What is the correct reading frame for the  
following mRNA sequence?**

**5'CGAUCAUGCGUUCGGGA...**

## 2. Ribosomes

- a. Translation
- b. Moves along the mRNA in the \_\_\_\_\_ that specifies a single amino acid.
- c. \_\_\_\_\_ of amino acids.
- d. There may be as many as \_\_\_\_\_ ribosomes in a growing *E. coli* cell.

<http://www.hhmi.org/biointeractive/rna/lectures.html>

### 3. tRNA has a cloverleaf structure

Fig 12.35 (8th) or 13.34 (9th)

b. Although there are 64 codons, there are \_\_\_\_\_ because \_\_\_\_\_ have no corresponding tRNA and the anticodon of some tRNAs can \_\_\_\_\_ (e.g. The anticodon 3'CCG5' can recognize both \_\_\_\_\_) This is called \_\_\_\_\_

4. Initiation of translation

a. In prokaryotes, translation begins while mRNA is still being \_\_\_\_\_

Fig 12.34 (8th) or 13.33 (9th)

\*Not to scale!

b. The 30S subunit of the ribosome binds to a sequence on the mRNA called the **Shine-Dalgarno sequence**.  
c. At the first **start codon** beyond the ribosome-binding site, an **initiation complex** consisting of the 30S ribosomal subunit, a tRNA carrying an **initiator tRNA** and proteins called **initiation factors** come together.

The subunit then joins the complex, IF-2-GTP hydrolyzes GTP and the initiation factors dissociate from the complex.

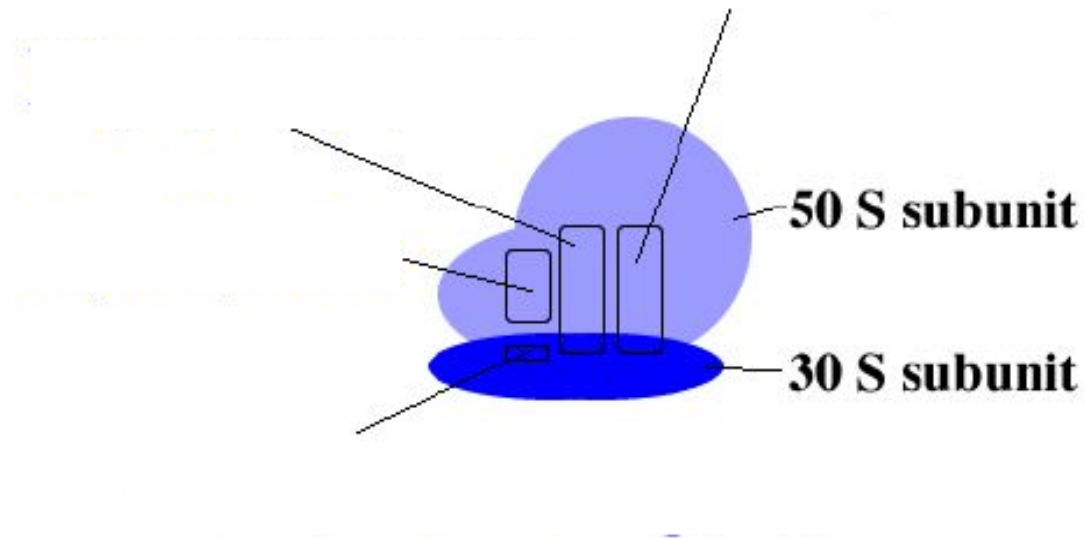

*The only time AUG serves as the start codon is when it is downstream from a ribosome-binding site (Shine-Dalgarno sequence). Otherwise it just encodes for methionine.*

*A ribosome binds to the following mRNA molecule at the site indicated by the dark box (Shine-Dalgarno sequence). Determine where translation will start and what are the first three amino acids that will be incorporated into the polypeptide?*

5' ████████GCCGGAAUGGUCAUGGGAAACC... 3'

5.

a. Several binding sites on the 70S ribosome play a role in the elongation process:

b. The Process:

1.) The initiating tRNA and its f-Met residue

2.) A tRNA carrying the amino acid that corresponds to the

3.) The f-Met bound to the tRNA in the P-site is the amino acid carried by the tRNA in the A-site.

to

4.) = the ribosome advances the distance of one codon and the tRNA and f-Met

5.) The tRNA and amino acid that had been in the A-site now occupy the E-site. The A-site is momentarily vacant but is quickly filled by a

c. NOTE: The same mRNA can be translated by several ribosomes at once. Many ribosomes on an mRNA = or just

## 6. Termination

a. Elongation is terminated when the ribosome reaches a

b. Proteins called **release factors** free the polypeptide by breaking the bonds between the last amino acid and its tRNA.  
c. The ribosome **dissociates** of the mRNA and **dissociates** into its 30S and 50S components.

## 7. Post-translational Modification

Proteins may be modified by the addition of a \_\_\_\_\_ or a \_\_\_\_\_  
\_\_\_\_\_ may help some proteins to fold into their final, functional  
shape.

## II. Eukaryotic Gene Expression

A. Eukaryotes have \_\_\_\_\_ RNA polymerase.

B. The \_\_\_\_\_ in eukaryotes differ.

C. Eukaryotic mRNAs are more often \_\_\_\_\_ after transcription.

1.

Shortly after transcription begins, the 5' end of the transcript is "capped" by the \_\_\_\_\_.

2.

Before transcription has been terminated, the mRNA is cleaved at a particular sequence and a series of \_\_\_\_\_

3. Modifications likely help to \_\_\_\_\_ and \_\_\_\_\_.

B. The structure of eukaryotic genes are commonly interrupted by

1. Both exons and introns are transcribed to generate the
2. The introns are removed by
