# LIGHTING

In the Science Initiative Building there is a high amount of windows to improve passive heating throughout the structure. On the southern facade, Low E glazing is applied to all windows to optimize solar heating and cooling. The Glazing is applied at different levels throughout the structure to maximize solar efficiency. In addition, the building's architectural layout maximizes natural light exposure while minimizing heat gain, contributing to a more sustainable and comfortable indoor environment

This structure is designed in a open layout to maximize the natural light capabilities of the structure. It was designed this way to accommodate the open layout classrooms and collaborative work environments throughout the building. This approach enhances both the ambiance and the productivity of the spaces, creating an inviting and dynamic atmosphere for occupants.

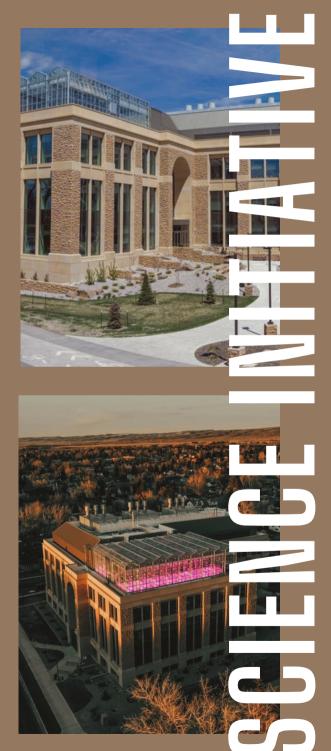

#### Additional Information

- Concept changed from modern architecture to stonework, to match campus aesthetic
- Sourced limestone exterior out of Utah
- Designed around LEED Silver Standards
- ROI is less than 10 years
- Art & sculpture was integrated into construction costs
- Polished concrete flooring was driven by the custodial staff due to its high durability, easiness to clean, and the reduction of toxic adhesives

## SUSTAINABLE DESIGN

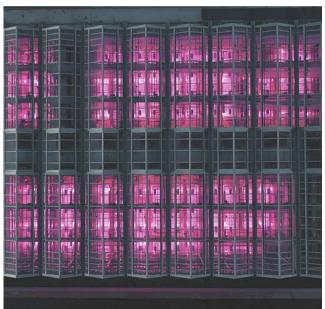

87% of Energy is Recovered
3 Advanced Energy Recovery Units
13% Heating Costs in comparison to
pre-existing campus structures

## Building Envelope-"The Perfect Envelope"

One of the most impressive aspects of the science initiative building is its envelope. A building envelope is what physically separates the interior and exterior environments from one another. Featuring exemplary vapor barriers, insulation, air gaps, and building cladding. This envelope protects its inhabitants and mechanical systems from wind, rain, snow. and temperature fluctuation, which is something we deal with all the time in Wyoming! The building envelope serves as a testament to the integration of cutting-edge technology and architectural design principles. Incorporating features like smart sensors and automated shading systems, it adapts dynamically to environmental changes, optimizing indoor comfort levels while minimizing reliance on mechanical heating and cooling systems.

#### Greenhouse

Another interesting feature that the Science Initiative building has is the greenhouse that lies on top of the structure. It is around 6,000 square-feet, has twelve separate greenhouses and two walk-in growth chambers. The greenhouse has a very advanced heating and cooling system that can emulate various climates. to grow a wide variety of plant species Although, those advancements do have pitfalls, the greenhouse is highly inefficient because it burns so much fuel during the cold season. Furthermore, the greenhouse's inefficiency during the cold season underscores the need for ongoing research and innovation in sustainable energy solutions to mitigate its environmental impact.

In the science Initiative Building about 25 million dollars of the 80 million dollar budget went to the mechanical systems, and about 5 million of that went to the energy recovery system alone. While that may seem like a costly expense, energy efficiency is never compromised when building new structures on campus. The Science Initiative Building runs off the campuses new central energy plant, which made the switch from a steam to a hot water system. This transition not only enhances energy efficiency but also significantly reduces the building's carbon footprint, aligning with the university's commitment to sustainability. The investment in advanced mechanical systems displays the institution's dedication to creating state-of-the-art facilities that prioritize both environmental responsibility and technological innovation.
