Lecture 20 (Chapter 5 and 37): Viruses

I. A brief history

I. General Characteristics of Viruses of Animals

A. Viruses are within living cells.

that can multiply only

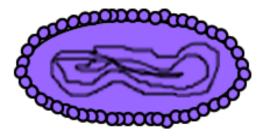

B. Virion size

Viron size ranges from

making them and making them

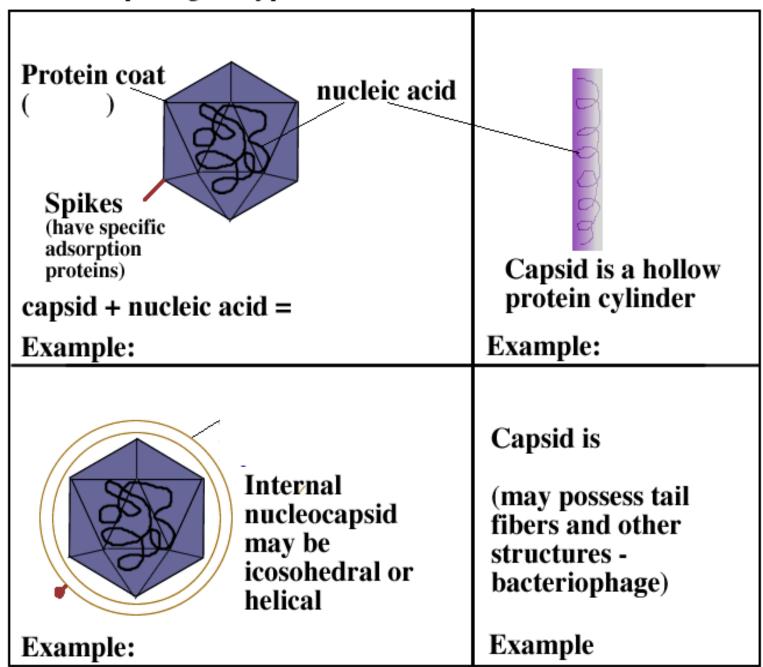

impossible to view on a regular light microscope.

Increasing virion size

C. General morphological types

II. Nucleic acids

A. May be

DNA or RNA. May

be linear or circular.

- Most DNA viruses use
- Most RNA viruses use ssRNA
 - a. may be identical to the mRNA and thus called the
 - b. may be complementary to the mRNA and thus called the

B. viruses (e.g. the influenza virus) have several molecules of RNA carrying different genetic information.

C. Viral genes must encode for three things:

1. The (early genes).

2. The synthesis of the viral (late genes).

3. The of the virus into and out of the host cell.

a. When the virus is outside the host cell, it is in a

called a

b. When the virus is inside the host cell, it is actively using the host cell's replication and expression machinery. At this point the virus is in the

III. Classification / Groupings of Animal Viruses

A. Based on genome structure, virus particle structure and presence or abscence of an envelope, animal viruses can be classified into families. We will look at examples of a few of these families.

Some animal vi	ruses containing <u>a single mole</u>	cule of ssRNA:
Family	Cartoon of virion (description of structure)	Example
Picornaviridae	Icosahedral Naked	Poliovirus Rhinovirus (common cold)
Togaviridae	Icosahedral Enveloped	Yellow fever virus Dengue virus West Nile virus (all in genus Flavivirus)
Coronaviridae	Helical Enveloped	Respiratory viruses SARS virus
Rhabdoviridae	Helical Enveloped	Rabies virus
Filoviridae	Helical Enveloped	Ebola virus

Puma:Users:rwatson:Desktop:Gen_micro_lectures:lecture20_viruses:Lecture20_f11:Lecture20_f16, Nov 6, 2013

Some animal viruses containing a segmented RNA genome:				
Family		on of virion ption of structure)	Example	
Orthomyxoviridae		Helical (pleomorphic) Enveloped	Influenza virus	
Bunyaviridae	SHE SHE	Helical Enveloped	Hantavirus	
Retroviridae		Icosahedral Enveloped	HIV	

Puma:Users:rwatson:Desktop:Gen_micro_lectures:lecture20_viruses:Lecture20_f11:Lecture20_f1ed, Nov 6, 2013

Some animal viru	ses contai	ining <u>a dsDNA gen</u>	ome:	
Family		n of virion ption of structure)	Example	
Hepadnaviridae		Icosahedral	Hepatitis B	
Papovaviridae		Icosahedral	Papillomavirus (HPV)	
Herpesviridae		Icosahedral Enveloped	Herpes simplex virus (fever blisters) Varicella-zoster (chickenpox) Epstein-Barr (mononucleosis)	
Poxviridae		Complex Enveloped	Smallpox virus	

An animal virus containing a ssDNA genome:			
Family	Cartoon of virion (description of structure)	Example	
Parvoviridae	Icosahedral	Parvovirus	

^{*}Note: viruses are commonly referred to by only their <u>species name</u> which is the name of the <u>disease they cause</u>. The family and genus names are <u>italicized</u> but the <u>species</u> name is not.

B. Classification based on routes of transmission

Group	Route of entry	Example
Enteric viruses	Ingested on material contaminated by feces (fecal-oral route)	Poliovirus
Respiratory viruses	Enter in inhaled droplets and replicate in the respiratory tract	Influenza virus, Rhinoviruses (colds), SARS virus
Zoonoses	Transmitted from animal to human or another animal (often from arthropods to humans / other animals)	Rabies Arboviruses (West Nile)
Sexually transmitted viruses	Transmitted during sexual contact	Herpes simplex virus-2, HIV

IV. Reproduction of Animal Viruses

A.

- a. Virus has surface attachment proteins (sometimes more than one) that
- b. Host cell receptors are always and are usually (hormone receptors or surface immunoglobulins). Often the virus must bind to before it can enter the host cell.
- c. Because a virion must bind to certain receptors, often a particular virus can only infect a and most can only infect a

The envelope of the virion and the nucleocapsid is

The capsid protein and nucleic acids separate.
Fusion is generally promoted by a on the surface of the viron.

The virion adsorbes to the host cell with its protein spikes, is and is surrounded by a . The envelope of the virion then freeing the nucleocapsid. The nucleic acids and capsid proteins separate.

--	---------------------------------------	--	---

3. Replication of viral nucleic acids and proteins	<u>s-</u> This	from virus
--	----------------	------------

to virus. Viruses with large genomes require the use of

as they encode for most of

In contrast, the very small parvoviruses depend completely upon the

Generally viruses are

before replication begins.

 similar to the maturation step in the life cylce of lytic bacteriophages. Release

6.

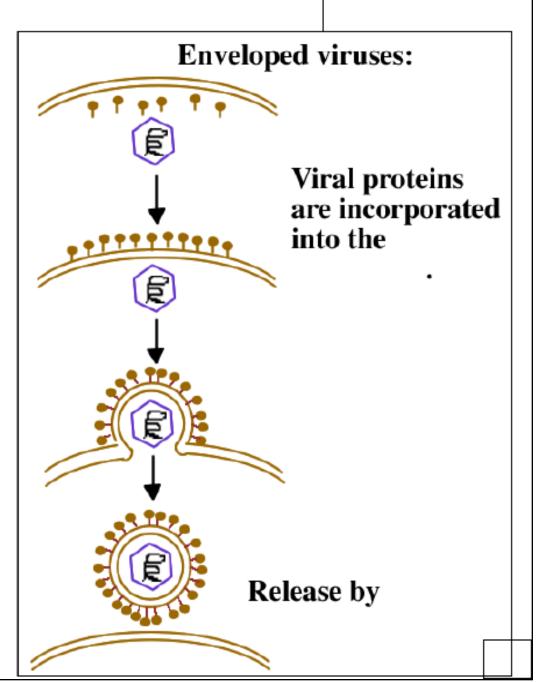

Naked viruses: Often host cells are

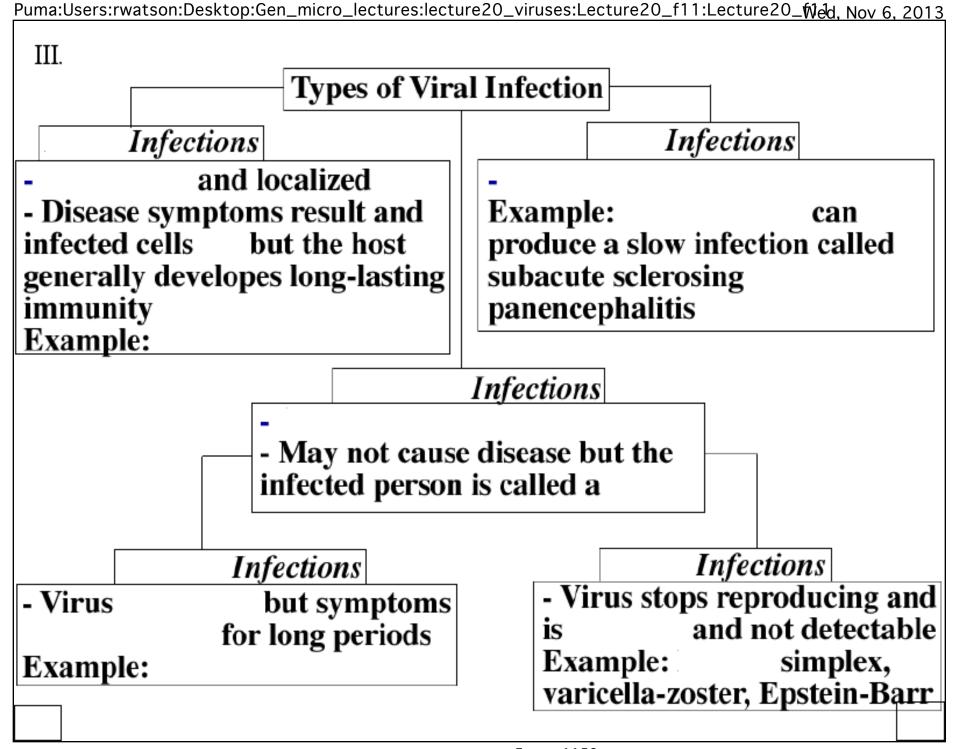

such a point that they die. After death, degredation of the host cell allows

Degredation by these enzymes allows

Alternatively the introduced viral proteins

by the immune system after which virions escape.

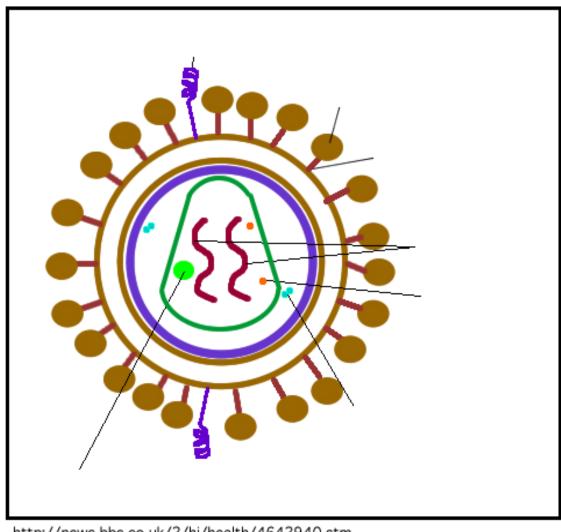

IV. HIV, the virus that causes AIDS

A. HIV is a member of the

family (Retro =

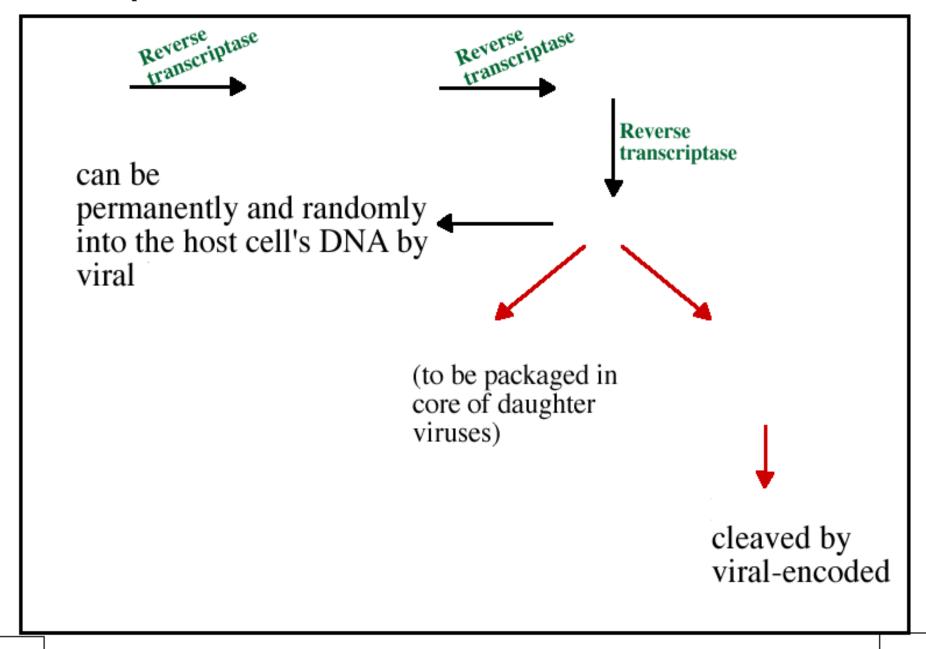

It has a cylindrical core inside its capsid that contains

http://news.bbc.co.uk/2/hi/health/4642940.stm The structure of HIV is variable
